

07-AWS-IAM-Security-Review-Checklist

AWS IAM Security Review Checklist

For cloud security review engagements covering AWS Identity and Access Management configuration.

1. Root Account

- ☐ Root account access keys do not exist (deleted, not just deactivated)
- ☐ MFA enabled on root account (hardware key preferred)
- ☐ Root account not used for day-to-day operations (verify via CloudTrail)
- ☐ Root account email is a monitored group alias, not an individual's inbox
- ☐ Billing/account alerts configured for root account activity

2. IAM Users

- ☐ MFA enforced for all IAM users (especially console access)
- ☐ No shared/generic IAM user accounts
- ☐ Unused IAM users identified and deactivated/removed (check `GetCredentialReport`)
- ☐ Password policy enforced (length, complexity, rotation, reuse prevention)
- ☐ Access keys rotated regularly (≤ 90 days) and unused keys removed
- ☐ No access keys embedded in code, AMIs, or configuration files

3. IAM Policies — Least Privilege

- ☐ No policies with `"Action": "*" and "Resource": "*"` (wildcard admin) unless explicitly justified
- ☐ AWS managed policies reviewed for over-permissiveness vs. actual need (prefer custom least-privilege policies)
- ☐ Inline policies minimized in favor of managed/reusable policies
- ☐ Use of IAM Access Analyzer to identify unused permissions and external access
- ☐ Permissions boundaries applied where delegated administration exists
- ☐ Service Control Policies (SCPs) applied at the Organization/OU level for guardrails

4. IAM Roles

- ☐ Cross-account roles use external ID and condition restrictions where applicable
- ☐ EC2/Lambda/ECS instance roles scoped to only the permissions the workload needs
- ☐ No long-lived credentials used where a role/temporary credential would work (e.g., EC2 instance profiles instead of embedded keys)
- ☐ Trust policies reviewed for overly permissive `Principal` fields (avoid `"Principal": "*" without conditions`)
- ☐ Role session duration set appropriately (not unnecessarily long)

5. Groups & Delegation

- ☐ Permissions assigned via groups, not directly to individual users
- ☐ Admin group membership minimized and reviewed regularly
- ☐ Break-glass/emergency access procedure documented and tested

6. Federation & SSO

- ☐ AWS IAM Identity Center (SSO) or federated identity used instead of numerous individual IAM users, where feasible
- ☐ SAML/OIDC trust configuration reviewed for correctness and least privilege
- ☐ Session duration and re-authentication requirements appropriate for sensitive roles

7. Logging & Monitoring

- ☐ CloudTrail enabled in all regions, logs sent to a centralized, access-restricted S3 bucket
- ☐ CloudTrail log file integrity validation enabled
- ☐ IAM-related CloudTrail events monitored via CloudWatch/SIEM (e.g., `CreateUser`, `AttachUserPolicy`, `CreateAccessKey`, root logins)
- ☐ AWS Config rules enabled to detect IAM drift (e.g., `iam-user-mfa-enabled`, `iam-policy-no-statements-with-admin-access`)
- ☐ GuardDuty enabled to detect anomalous IAM/credential activity
- ☐ Alerts configured for root account usage, policy changes, and new access key creation

8. Resource-Based Policies

- ☐ S3 bucket policies reviewed for public access; S3 Block Public Access enabled account-wide unless explicitly required
- ☐ KMS key policies reviewed for overly broad grants
- ☐ Lambda resource policies reviewed for unintended public invoke permissions
- ☐ Secrets Manager / SSM Parameter Store access scoped per application, not broadly shared

9. Third-Party & External Access

- ☐ All third-party/vendor IAM roles reviewed for scope and external ID usage
- ☐ Cross-account trust relationships documented and periodically re-validated
- ☐ No wildcard trust policies allowing any AWS account to assume a role

10. Governance & Review Cadence

- ☐ IAM Access Analyzer findings reviewed and remediated regularly
- ☐ Periodic access recertification process in place (quarterly recommended)
- ☐ IAM changes go through code review / IaC pipeline (Terraform/CloudFormation) rather than manual console changes where possible
- ☐ Least-privilege policy generation tooling used (e.g., IAM Access Analyzer policy generation) when scoping new roles
